Data Pre-Processing & Preparation Phase

Before generating the visual analytics, the raw Product Positioning.csv dataset underwent a rigorous pre-processing pipeline to ensure data integrity and accuracy. Because the primary analytical engine is Tableau, the majority of this cleaning and transformation was handled directly within the Data Source layer.

1. Data Cleaning & Standardization

- **Null Value Handling:** Scanned the dataset for missing values in critical columns (e.g., Sales Volume, Price, Foot Traffic). Incomplete transactional rows were filtered out to prevent skewed averages.
- **Data Type Casting:** Ensured that numerical fields (Sales Volume, Price) were correctly cast as Integers/Floats, and categorical fields (Product Category, Placement Zone) were cast as Strings, allowing the visualization engine to aggregate them properly.
- **Duplicate Removal:** Verified that no duplicate transactional records existed that could artificially inflate the sales figures for specific regions.

2. Data Transformation (Feature Engineering)

- **Calculated Fields:** Created custom metrics within Tableau to derive deeper insights. For example, generating a "Total Revenue" field by multiplying [Price] by [Sales Volume].
- **Standardization:** Normalized categorical text inputs (e.g., ensuring consistency in category names like 'Electronics' vs 'electronics') so that the group-by functions in the visualizations worked flawlessly.

3. Data Aggregation

- **Roll-up Summaries:** Aggregated individual, row-level transactional data into higher-level macro summaries (e.g., "Total Monthly Sales per Placement Zone") to allow executives to view high-level KPIs before drilling down into granular data.
